Dr. H. B. Woodruff  
Research and Development  
Merck and Company  
Rahway, New Jersey

Dear Dr. Woodruff:

I wish I could answer your letter of the 20th more optimistically, but there is a great deal of work still to be done on the genetics of actinomycetes.

The experiments I've completed with *Streptomyces griseus* point rather clearly to the occurrence of heterokaryosis. The spores from heterokaryotic colonies segregate out the parental types rather cleanly. One can place a fair degree of confidence in spore-isolation as a means of securing initial genetic purity. Whether recombination occurs at all is a more difficult question. Auxotroph combinations have given prototrophic cultures, but most of these probably stemmed from the resynthesis of heterokaryons. A few stable prototrophs may have been recombinants, but spontaneous reversion has not been excluded. I had some difficulty in introducing second auxotroph mutations to use as markers, owing to the familiar loss of ability to sporulate well on repeated transfer.

At the moment, I am occupied with another problem, but hope to return to *Streptomyces* before too long, especially if a suitable graduate student should express an interest in it this fall. I would imagine that genetic control of your fermentation cultures would be a matter of the utmost importance to you. If the pace that I have been able to adopt for this work is too slow (as it should appear to you, by my reasoning), I will be glad to collaborate with your group on its development. At present, I would say that a good deal more fundamental research needs to be done before applications will be feasible, but I cannot see how it could fail to be worth your consideration.

Yours sincerely,

Joshua Lederberg

Associate Professor of Genetics
